## Revolution of Jupiter's Moons

Turn in one copy of this lab with each group member's printed name and signature. By signing, you certify that you have actively participated in the exercise and have put forth effort in equal share to your fellow group members.

## Printed Name

$\qquad$
路

1. Io is the closest moon to Jupiter. How can you tell which one is lo (aside from randomly clicking to find out)?
2. Compare lo's motion when it is close to Jupiter to when it is far from Jupiter.
3. Why does lo appear to move this way? (Hint: what would their orbits look like if you viewed them from above?)

After making the graphs
4. Was it easier to draw the curve for Callisto or for Europa? Why?
5. Can you draw a curve for lo? What could you do observationally to make it easier to find lo's curve?

Table 1

| Moon | a <br> (Jupiter diameter) | P <br> (days) | a <br> (A.U.) | $\mathbf{P}$ <br> (years) |
| :--- | :--- | :--- | :--- | :--- |
| lo |  |  |  |  |
| Europa |  |  |  |  |
| Ganymede |  |  |  |  |
| Callisto |  |  |  |  |

## Table 2

| Moon | Mass of Jupiter <br> (solar masses) |
| :--- | :--- |
| Io |  |
| Europa |  |
| Ganymede |  |
| Callisto |  |
| Average |  |

6. Compare the answers you got for the mass of Jupiter from the different moons. Did you get similar or different answers?
7. The mass you finally found is in units of solar masses. In other words, Jupiter is about $1 / 1000^{\text {th }}$ the mass of the sun. Do you think Jupiter is big enough for its mass to matter when using Kepler's $3^{\text {rd }}$ Law to find the mass of the Sun? Why or why not?
